Introduction

In choosing a sorghum hybrid for silage production it is critical to know the agronomic and nutritional characteristics of specific hybrids. This trial, as well as those conducted in previous years, attempts to provide a summary of those characteristics that should be considered when choosing a hybrid for hay or silage production. The study forage sorghum and sorghum-sudangrass hybrids with and without the brown midrib (BMR) and photoperiod sensitive (PS) traits. Corn silage has long served the region well, producing consistent, high quality silage. As part of this study a popular corn silage hybrid was planted adjacent to the sorghum trial for comparison. The corn was irrigated and fertilized identically to the sorghum.

Methods and Materials

The trial was made up of 97 hybrids provided by seed companies. Several male sterile hybrids were included. These were all capable of producing grain due to cross-pollination that occurred in the field with other hybrids. Seed companies will provide pollinator seed for male sterile hybrids if desired. The hybrids were planted in a randomized block design in four row plots planted on 30-inch raised beds. Irrigation was applied by furrow. Irrigation scheduling was determined by monitoring gypsum blocks placed in the soil at depths of 1, 2, and 3 feet. Moisture blocks were read every two to three days and plots were irrigated when the average of the three moisture blocks fell below 60. A total of 12.2 inches of water was applied during the season along with a pre-irrigation of 6.5 inches. Rainfall totaled 9.5 inches during the growing season (May 21 – September 18). Additional rainfall of 5.6 inches from September 19 to October 9 likely helped the forage (silage) yield of the late maturing sorghums as well as the grain yield of all hybrids. Each hybrid was harvested for forage yield when grain reached the soft dough stage. Photoperiod sensitive hybrids were harvested on the last harvest date of the season (Oct 13). Other cultural practices and study information are listed below:

Trial Location:	Bush farm located one mile north of Bushland, TX.
Cooperator:	Texas Agricultural Experiment Station.
Previous Crop:	Wheat.
Soil Type:	Pullman Clay Loam, pH = 7.4.
Plot Size:	Four, 30 inch rows by 25 ft.
Replications:	3.
Study Design:	Randomized complete block.

³ Res. Assoc., Crop Testing Program, TAMU College Station, Phone: 979-845-8505, Email: croptesting@tamu.edu.

Planting Date:	May 24, 2004.
Planting Rate:	120,000 seed/acre.
Seed Method:	John Deere Max-emerge Planter.
Fertilizer:	150 lbs/acre N and 40 lbs P205.
Herbicide:	One lb/acre atrazine applied immediately after planting.
Irrigation:	Furrow irrigated based on moisture block readings. A total of 12.2 inches applied during the growing season.
Silage Harvest Date:	Plots were checked weekly and harvested when grain was in the soft dough stage. Harvest dates ranged from September 9 to October 13 and are reported in Table 2.
Grain Harvest Date:	Over a three week period in November.

Data Collected:

- Plant height (ft) at silage harvest.
- Lodging at silage harvest. Percent of fallen or significantly leaning plants per plot.
- Silage yield. Collected at or near the soft dough stage from 10 feet of row. Yield is reported at 65% moisture in tons/acre.
- Nutrient analysis: Whole plant sub-samples were collected from the yield sample immediately after harvest, chopped, and frozen. These sub-samples were sent to Dairy One Laboratory, Ithaca, NY for analysis. All nutrient constituents were adjusted to a 100% moisture-free basis.
- Grain yield was collected from 10 feet of row from each plot. Samples were thrashed and yield reported in lb/acre. No moisture correction was made.
- Nutrient Analysis Definitions

Crude Protein: 6.25 * % total nitrogen.

TDN: Estimate of total digestible nutrients

NDF: Neutral detergent fiber; cell wall fraction of the forage.

ADF: % acid detergent fiber; constituent of the cell wall includes cellulose and lignin; inversely related to energy availability.

NEL: Estimate of Net Energy for lactation.

NEm: Estimate of Net Energy for maintenance.

NEg: Estimate of Net Energy for gain.

IVTD: % in vitro true digestibility; positively related to energy availability.

IVTD/ac: %IVTD * forage yield (lbs DM/ac).

Corn Silage Trial (Methods and Materials)

A popular corn hybrid, NC+ 7117, was planted adjacent to the sorghum silage trial for comparison. The corn was planted on May 25 in a 200-ft strip on four 30-inch rows at 26,000 seed/acre. Atrazine was applied immediately after planting at 1.0 lb/acre for weed control. The corn was fertilized and irrigated exactly the same as the forage sorghum trial. This differed from previous years' where corn was fully irrigated based on moisture block readings. Three samples were collected for yield and nutrient composition determination when the kernel milkline had advanced 1/2 to 2/3 of the way down the kernel.

Results and Discussion

A summary of yield, agronomic traits, and nutrient composition, are reported by groups of different sorghum and sorghum-sudangrass types along with corn in Table 1. See Table 2 for a listing of each specific hybrid's agronomy characteristics, yield, and nutrient composition.

Overall weather conditions were excellent throughout most of the summer. Average forage yield was up compared to 2003, but less than what was achieved in 2001 and 2002. Stand counts collected 30 days after emergence showed an average of 29,450 plants/acre, considerably less than the 120,000 seed/acre planted (data not shown). Low plant population likely contributed to the forage yields being less than observed in other years. The photoperiod sensitive hybrids were particularly vulnerable to low plant populations because of their lack of tillering ability.

BMR forage sorghum hybrids yielded 14.3% less than non-BMR forage sorghums (Table 1). This was consistent with what we have observed in previous years. PS non-BMR hybrids had the highest forage yields, but when the BMR trait was added to the PS hybrids yield was reduced in both the forage sorghums and sorghum-sudangrasses. Lodging was generally not a problem with only a couple of BMR forage sorghums and sorghum-sudangrass hybrids having significant lodging scores at harvest (Table 2).

¹⁾ Number in parenthesis is the number of hybrids that make up each sorghum or corn type. BMR = Brown midrib, PS = Photoperiod sensitive.

²⁾ IWUE = Irrigation water use efficiency. Tons of forage produced (65% moisture) per inch of in-season irrigation water.

BMR and non-BMR forage sorghum yield per acre-inch of irrigation water applied in-season (IWUE), was similar to what was observed in 2001 and 2002. However, in contrast to previous years, corn IWUE was considerably better at 1.6 tons/ac-inch of water. This year the corn was irrigated exactly like the forage sorghum. In previous years corn was fully irrigated and produced a higher overall yield, but produced less tonnage per inch of in-season irrigation water. This was also a good year for corn with overall cooler than normal temperatures and timely rainfall received.

As seen in previous trials, hybrids containing the BMR mutation, on average had higher digestibilities compared to hybrids of the same type without the BMR trait. As also seen in previous trials, the range of digestibilities within the BMR types or the non-BMR types resulted in overlap among the types. The improved digestibility of the BMRs reflects the lower lignin content of the forages. It is important to note that individual hybrids, both with and without the BMR mutation, had digestibilities similar to corn. The photoperiod sensitive varieties have a lower digestibility compared to other hybrids, possibly as a result of higher lignin content. However, the relative difference between BMR and non-BMR hybrids is greatest for the photoperiod sensitive varieties.

Table 2. 2004 Comparison of sorghum hybrids for agronomic characteristics, yield, and nutrient composition.
