COMPOSTING: WTAMU group has alternative plan for disposal of carcasses

By Patricia Gardner

Members of Congress adjourned Friday to campaign for the upcoming November elections and leaving work until their return. One issue uppermost on Texans' minds left unattended by them was the American Horse Slaughter Prevention Act, brought by a civil group and seriously affecting how old, sickly or useless horses will be treated in the future. The act, which bans the slaughter of horses for human consumption, was approved in the House on Sept. 7 by a vote of 263 - 146 before being passed over to the Senate.

If the Senate approves the controversial bill, thousands of horses could be left with no final resting ground. Approximately 90,000 horses, or 1 percent of the U.S. horse population, are slaughtered annually, said Dr. Lance Baker, West Texas A&M University associate professor of animal science. "If they don't go to slaughter, they will have to go somewhere else," Baker said. "This bill is purely emotional, with supporters not considering what would happen to unwanted or dead horses." The options for dealing with a carcass are burial, rendering, landfill disposal, incineration, composting or bio-digesting, he said. Many of these are costly, and a horse owner often has to pay to both put the horse down and for its disposal, instead of getting money for the animal.

Here in the Panhandle, that can run from $100-$150 for putting down the horse by a veterinarian, plus a cost of around $125 to dispose of the animal at the landfill, Baker said. Previously, Hereford By Products would pick up dead horses, but since December 2005, they no longer accept equine carcasses. Another alternative, burial, is tied to environmental laws regulating proximity of water sources, etc., and burning of the carcasses intertwines with local burn bans. Besides, Baker said, horse carcasses have to get really hot to efficiently burn them, and that must occur in an approved incinerator.

Though it's not an alternative to a proper burial for a loved animal, West Texas A&M University has found a way to respond to the dis...

Horses

posal of dead horses.

Composting may be an environmentally friendly option that fits in the "circle of life" frame of mind and may be less emotional to horse owners, two area researchers said. Large-carcass composting is a growing and accepted practice among feed yards and dairy farms, said Dr. Brent Auvermann, Texas Agricultural Experiment Station agronomic engineer who has researched the process for about five years. "Since we had already done some work with dairy cattle that weigh about 1,400 pounds, a horse at 1,000 pounds wasn't much different," he said.

"The longer the carcass, the higher the stakes. It is critical that whoever does it, does it right," Auvermann said.

Auvermann, Baker and West Texas A&M graduate student, Laurie Brown begaungnudging a composting trial on horses last winter, using dead horses provided by area veterinarian and that would otherwise have gone to the landfill.

The trial tested three different formulas of composting material designed by Auvermann: 100 percent stall cleanout (horse manure and bedding), 50 percent cattle manure and 50 percent waste hay; and 50 percent stall clineout and 50 percent cattle manure. He said he prefers the two mixes to the 100 percent stall clineout.

The carcass is laid on a bed of chopped hay and then covered completely with the composting material. Large animal composting work is not if the process also began before the carcass is added, Auvermann said. From that point, moisture is a key. Auvermann said it would be better to err on the side of too dry than too wet.

"Add water until a handful of the mixture squeezed hard does not result in droplets of water, but does leave a sheen of water on the glove," he said.

A good indication the composting process is working correctly is temperature. Auvermann said the temperature should start rising within 12 to 24 hours and reach a level between 131 degrees Fahrenheit and 155 degrees Fahrenheit and stay in that range for several weeks to a month to efficiently decompose a carcass. The temperature should be tested with at least a 48-inch temperature probe in several locations throughout the pile, he said.

In the Baker pile, turning three months, at which time Baker said only a few large bones were identifiable. By six months, nothing was identifiable. The optimum time to wait before making the first turn with larger animals is five to six months, Auvermann said. A large carcass would wait from seven to nine months to compost completely, at which point it can be used as a soil fertilizer. The phosphorous level will be about 20 to 25 pounds per dry ton, and might contain 20 pounds to 35 pounds of nitrogen, though the nitrogen volatilizes off, Baker said.

"This is well suited to cotton in terms of the nitrogen-phosphorus-rhizobial," Auvermann said, adding cotton gin trash would be an excellent ingredient to put into the composting mix. The compost must go through three phases before it is a valuable product, he said. The first phase, curing, is important because it lets the last intermediate compounds be converted to non-phytotoxic compounds. "Maturity testing is a good idea," Auvermann said. "When you put compost on plants, if it is not mature, it may compete with the plants for nitrogen. It also may not be the plant if it is too hot with phytotoxic compounds."

He suggested trying a small amount with potting soil in a seedling tray to see if the seed would germinate and grow, or using a maturity test kit. Auvermann said several other options were to test the material as a Class A biosolid for roadways and to help establish turf grass, or it could be used in the bioenergy arena. The material could be gasified and burned after it is composted.

Both Auvermann and Baker said the small individual horse owner might not be interested in the composting of a horse carcass, but it could serve as a more soothing experience than the alternatives.

"All horses are going to die; it's a matter of how they are disposed of that is up to us," Baker said. "If you look at it (composting) environmentally and politically it works. It's the whole circle of life thing. You grow the grass to feed the animals and then turn around and use them to do the same thing for the next generation."
