

**2024 Texas A&M AgriLife Bushland Forage Sorghum Silage Trial**

Jourdan Bell, Carla Naylor, Kevin Heflin, Nick Porter, Jessica Smith, Juan Piñeiro,  
Ronnie Schnell, Katrina Horn, and Thomas Marek

The 2024 Texas A&M AgriLife Research and Extension Forage Sorghum Silage Trials evaluated 74 sorghum hybrids representing forage sorghum (n=52), sorghum sudan (n=12), and grain sorghum (n=10) under center pivot irrigation at the Texas A&M AgriLife Research Farm at Bushland, Texas. Hybrids were submitted by seed companies on a per fee basis except for the grain sorghum (DKS 36-07 and P84G62) and corn hybrid checks. The corn checks (n=3) provide a direct comparison between the forage production potential of corn and sorghum in the same production environment. The 2024 production season (June through August) was marked by hot and dry conditions (Fig. 1). The trial was irrigated at approximately 50% of the corn evapotranspiration requirement. Deficit irrigation coupled with limited rainfall during this period resulted in water stress and overall reduced yields; however, the maximum yielding hybrid was Supra Sorghum X at 11.4 tons DM/acre (Table 3). Data affirms that sorghum maintains yield and quality under water limited conditions.

**Agronomic Information**

Previous Crop: Corn

Planting Date: June 6, 2024

Forage Sorghum Seeding Rate: 80,000 seeds/acre

Corn Silage Seeding Rate: 32,000 seeds/acre

Fertilizer: Pre-plant strip-tilled 100 lbs. N/ac (4-8-2024) Preplant Soil Analyses (0-36 in. 198.5 lbs N/ac)

Cultivation: Pre-plant cultivation sweep plow/rotary hoe (5-31-2024 and 6-5-2024)

Herbicide: Post-emergent: Warrant 48 oz/ac plus Atrazine 1lb/ac plus 2,4-D 5 oz/ac (6-21-2024)

Post-emergent: Huskie oz/ac plus Atrazine 1lb/ac plus AMS 1 lb/ac (7-9-2024)

Insecticide: Sivanto 10 oz/ac with pre-plant strip-tilled N (4-8-2024)

Sivanto 7 oz/ac at 20 gpa with boom sprayer (7-9-2024)

Sorghum aphids (Sugarcane Aphids) identified (8-9-2024)

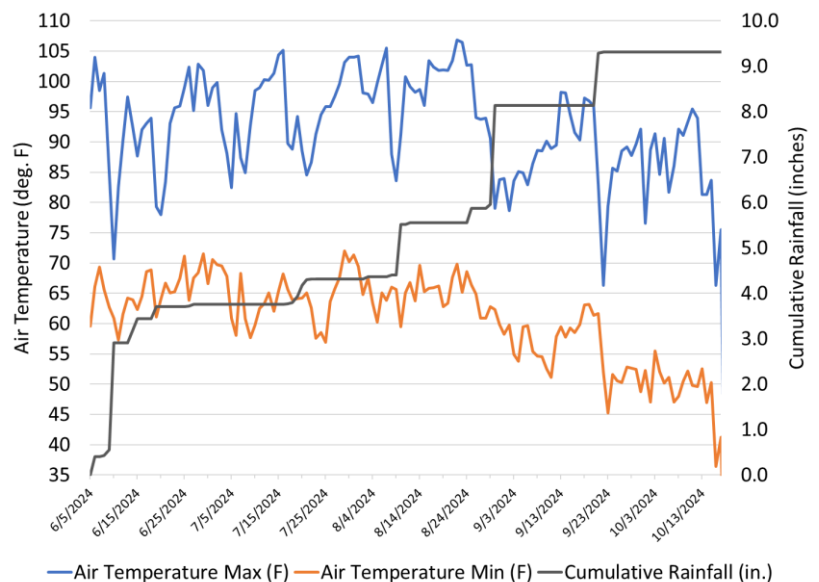

Sivanto 10 oz/ac Chemigated (8-15-2024)

In-season Irrigation (Jun 6 - Aug 17): 11.0 inches

In-season Rainfall (Jun 6 - Aug 17): 9.3 inches

Hybrids were blocked according to their marketed maturity class so that forages within each block could be mechanically harvested for yield when grain reached soft dough. All hybrids were replicated three times. Uniform sub-samples were collected for dry matter and nutritional composition from all plots. A sub-sample of the chopped forage was dried at 221°F (105°C) to determine harvest moisture. Reported yields were corrected to 65% moisture and on a dry matter basis. A 600-gram sample was submitted to Cumberland Valley Analytical Services in Waynesboro, PA forage nutritional analyses using near infrared reflectance spectroscopy (NIR). Forage constituents are reported on a dry matter (DM) basis (Table 4).

Hybrid maturity is an important consideration when making hybrid selections. It is important

**Figure 1.** Daily maximum and minimum temperatures along with cumulative rainfall from planting at the field site.

for producers to be aware that the marketed maturity class (e.g. early, medium, etc.) is not stable across all production environments, so producers should inquire about hybrid maturity in their production environment. Maturity and physiological development are influenced by day length, abiotic (moisture and heat) stress, and biotic (insect and disease) stress. The days to half-bloom (HB) provides an indication of maturity. The HB date is when 50% of the plants, in the area of observation, are blooming (Vanderlip, 1993). When evaluating a single plant, HB is when flowering has progressed half-way down the head.

Although the forage yield tends to increase with longer maturing hybrids, forage nutritional parameters may decrease because of greater exposure to abiotic and biotic stresses along with differences in hybrid physiological characteristics. Comparing broad averages for all sorghum hybrids in the 2024 Texas A&M AgriLife Forage Sorghum trial indicates that late maturing hybrids may need an additional 30 days to reach HB compared to early hybrids (Table 1).

Growing degree day (GDD) accumulation can often be a concern for late planted sorghum or sorghum grown in northern production environments. Cumulative GDDs are a function of planting date and daily (maximum and minimum) temperatures. Calculated GDDs were determined using a 50 °F base (Vanderlip and Reeves, 1972) and an upper limit upper-limit of 100 °F as recommended by Gerek et al. (2003). Roozenboom and Prasad (2019) reported the range of cumulative GDDs required for typical grain sorghum hybrids to reach physiological maturity at Manhattan, Kansas were 2588-3038 using these upper and lower limits. However, there is negligible research reporting the necessary GDDs for forage sorghum hybrid development, but forage sorghum grain should not reach physiological maturity (i.e. black layer) if harvested to optimize forage nutritive value of any forage type (cured hay or silage). The calculated GDDs for each maturity class range evaluated in the 2024 Texas A&M AgriLife Forage Sorghum Silage trial indicates there is not a risk of insufficient GDD accumulation for early to late maturing hybrids planted in June and harvested at soft-dough for silage (Table 1).

**Table 1.** The average days to specific physiological stages, accumulated growing degree days (GDDs) from planting, and yield and nutritive values on a DM basis for suggested maturity classes based on days to half-bloom (HB) for sorghum hybrids evaluated in the 2024 trial.

Maturity Class	Days to HB Range	Days to Boot	GDDs	Days to HB	GDDs	Days to SD	GDDs	Yield (tons/ac)	% CP	% NDF	% ADF	% Lignin	% Starch	% WSC
Early	<70	53	1520	65	1902	92	2672	4.9	10.8	42.8	26.0	3.3	22.2	34.0

Water availability should be a consideration when selecting a longer maturing hybrid. Total seasonal crop water use (combination of soil water, rainfall, and irrigation) was evaluated for select hybrids representing five of the evaluated maturity classes (Table 2). Total crop water use was significantly different between the maturity classes; late and photoperiod sensitive hybrids used approximately 5 more inches of water.

**Table 2.** Total crop water use for select hybrids representing five of the evaluated maturity classes. Soil water use was determined gravimetrically in each plot. Soil samples were collected prior to planting and on the day of harvest for each hybrid. Precipitation was measured at a weather station adjacent to the research field.

Hybrid	Maturity	Soil Water Use	Irrig.	Precip.	Total Crop Water Use
		inches			
F71FS72 BMR	Early	9.2	9.2	6.0	24.3
23015+	Med-Early	8.7	9.2	8.1	26.1

<b>Average</b>					27.2
<b>P-value</b>					<.0001
<b>CV (%)</b>					0.6
<b>LSD</b>					0.3

**Forage Nutritive Analyses Defined:**

**CP:** Crude Protein

**ADF:** Acid Detergent Fiber; a fraction of the cell wall includes cellulose and lignin.

**NDF:** Neutral Detergent Fiber; cell wall fraction of the forage includes cellulose, hemicellulose and lignin.

**NDFD30:** NDF digestibility; estimated fiber digestibility after 30 hours.

**Lignin:** A structural material for cell walls and thus important for plant standability. Lignin is almost completely indigestible.

**Starch:** A carbohydrate primarily located in the grain. Starch availability is a function of harvest timing and berry processing.

**WSC:** A measurement of simple sugars (glucose, fructose, and sucrose) and fructans. WSCs accumulate in the stalk until anthesis. After anthesis, they remobilize to the grain. WSCs are important for fermentation as they are used during the development of lactic acid.

**TDN:** % Total Digestible Nutrients representing digestible protein, digestible crude fiber, digestible nitrogen free extract, and digestible fat.

**tons TDN produced per acre:** Represents the energy production under the evaluated management and environmental conditions. Calculated as % TDN x forage yield (tons/acre; DM basis) = tons of TDN produced per acre

Photoperiod sensitive hybrids were harvested on the last sampling date (October 9, 2024). Male sterile hybrids were randomized as part of the larger trial and pollinated by neighboring plots. The production of male sterile hybrids may not reflect yield and nutritive value in an isolated area. Grain yields for requested hybrids (Table 5) were collected following forage harvest and once grain reached physiological maturity. Grain yield data is annually submitted to the USDA-Farm Service Agency (FSA) to update the table of forage sorghum hybrids eligible for loan deficiency payment. Grain production can contribute significantly to forage yield and nutritional profiles, but the desired grain quantity varies depending on end-user-goals. Harvest Index, pound of grain per pound total biomass (forage + grain) provides an indication of the grain fraction of the total biomass yield. Statistical analyses were completed for sorghum hybrids using SAS 9.4. Adjusted least significant differences for multiple comparisons were determined using Tukey’s Honest

Significant Difference post hoc test. Effects and comparisons were determined significant at the 0.05 probability level.

Reported data and the discussion addresses broad averages for forage sorghums, grain sorghums, and sorghum-sudangrass hybrids evaluated in the 2024 trial as a fresh forage but managed for silage. It is not recommended that hybrid selection be made based on marketed forage type. While the marketed forage types provide an indication of potential quality and nutritive value, actual parameters vary for hybrids of the same forage type, and there is often an overlap among hybrids in these type categories. Because nutrient requirements vary between livestock classes, evaluated parameters provide a broad comparison of forage nutritive value in the respective production environment.

The authors are appreciative of student employees who provide valuable labor maintaining plots (Kylie Deaton, Emberly Spearman, Jose Gonzales Santiago, Tristen Reed, and Will McCartt).
